POPULATION, ENVIRONMENT AND HUMAN RIGHTS: A PARADIGM IN THE MAKING

GITA SEN AND ANITA NAYAR

INTRODUCTION: A TALE OF FOUR CITIES

Current controversies about population, environment and human rights can be traced back to pivotal United Nations Conferences of the early 1990s that occurred in four cities—Rio de Janeiro, Vienna, Cairo and Beijing. In the international policy arena, the early 1990s were flush with optimism engendered by vigorous civil society movements, the growing realization of democracy—particularly in Latin America after a long night of dictatorship—and perceptions that the era of hard structural adjustment programmes was giving way to a greater focus on poverty eradication and human development. The democratic processes of the 1980s strengthened the voice of powerful actors on the global stage—in particular, environmental groups, women’s rights organizations and human rights activists.

The UN conferences of the 1990s were the ground for cross-fertilization of ideas and strategies among these actors, sometimes synergistically and at other times through deep controversies. The 1992 UN Conference on Environment and Development (Earth

Summit) in Rio, and especially its ‘women’s tent’ (*Planeta Femea*) at the Non-governmental Organization Forum, saw day after day of intense debate about the links between population and environment among environmental activists (particularly from the global North) and women’s health groups that had begun to articulate a sexual and reproductive health and rights agenda. The 1993 Vienna World Conference on Human Rights saw the first explicit official recognition of women’s rights as human rights and of violence against women as a violation of those rights (UNWCHR 1993, Bunch and Reilly 1994). The Global Campaign for Women’s Human Rights had mobilized over three years to bring this about, and laid thereby the basis for the recognition of sexual and reproductive health and rights at the International Conference on Population and Development in Cairo the following year and at the Fourth World Conference on Women held in Beijing in 1995 (Sen 2006).

The close and sustained interaction of environmental activists and women’s rights groups (especially those focusing on sexual and reproductive health and rights) began to transform the hitherto Malthusian approach to population/environment linkages towards one based on human rights. This paper discusses the nature of this paradigm change away from a macro-level focus on population growth towards a more bottom-up and gender-sensitive approach based on women’s human rights, buttressed by the work of anthropologists and other social scientists. Understanding the nature of this paradigm change—and the role of women’s organizations in effecting it—is critical in the context of renewed debates within the processes marking the twenty years after both the Earth Summit and the International Conference on Population and Development.

POPULATION/ENVIRONMENT LINKAGES: A MALTHUSIAN REPRISE?

The three critical elements of a paradigm are its world view (as shaped by the values that guide the questions it asks), its internal consistency or logic, and its robustness with respect to evidence from both within and outside. Kuhn (1962) defined a scientific paradigm as the acceptance by a community of researchers of a common set of questions, a common basis of evidence, and a common approach to interpretation and analysis. Handa (1986) broadened Kuhn’s original frame to recognize the importance of world views (*weltanschauung*)—coherent systems of values and ideas—in shaping paradigms in both social and natural sciences. Not acknowledging the role of values in the making of paradigms imbues the latter with a false objectivity. Indeed it is the evolution of values, shaped by social movements and historical shifts, that quite often determines the change from existing to new paradigms. Furthermore, the robustness and durability of

a paradigm depends on its ability to explain other evidence that ‘intrudes’ so to speak from outside itself to pose a challenge. We will examine the paradigmatic challenges that have been posed to analysis of population/environment links, from this perspective.

The Malthusian approach to population/environment linkages was a dominant paradigm until it was transformed through the UN processes of the 1990s. In between, the field of technical demography and population studies grew and fuelled more sophisticated understanding of the demographic transition from high to low birth and death rates. There has been extensive debate on the factors that have fuelled this transition. These include the role of rising affluence and urbanization, cultural change, contraceptive availability and family planning programmes, as well as the role of women’s autonomy, literacy and education. Whether the predicted steady state global population of 9 to 10 billion is environmentally sustainable is really not known. Although Malthus’ 19th century thesis of population growth outstripping food supply was not stated in terms of its impact on the environment—a concept and terminology that evolved some hundred years later—its substance bears a striking resemblance to modern day concerns about the impact of population growth on food security. These were stated in the clearest terms in the ‘IPAT’ equation proposed four decades ago by scientists John Holdren and Paul Ehrlich (1971, 1974). Driven by the rising concerns of ecological scientists, they argued “the most elementary relation between population and environmental deterioration is that population size acts as a multiplier of the activities, consumption, and attendant environmental damages associated with each individual in the population. The contributing factors in at least some kinds of environmental problems can be usefully studied by expressing the population/environment relation as an equation: environmental disruption = population x consumption per person x damage per unit of consumption....” (1974).

This can be written as: $I = (P) (A) (T)$, where I = environmental impact; P = population; A = affluence measured as gross domestic product (GDP) divided by population; and T = technology measured as environmental impact per unit of GDP. Actually, IPAT is not strictly speaking an equation but a mathematical identity that is always true, which can be seen by re-writing it as: $I = (P)(GDP/P)(I/GDP)$.

Written in terms of growth rates, the relative rate of growth of I = the sum of the relative growth rates of P , A and T . Strictly speaking, while the growth rate of I can thus be decomposed into the growth rates of the other three variables, it is invalid to attribute causality to the terms in an identity.¹ The choice of variables to include in an identity can be made *a priori*, and in fact any variables can be chosen without ever invalidating the identity. This is a classic paradigm issue where the choice of questions asked and variables chosen depends on one’s world view.

The IPAT identity has been criticized because it treats all population subgroups as the same and ignores the role of distribution. It also assumes implicitly that environmental vulnerability is a constant. For instance the fact that high water consumption may be less problematic in a swamp than in a desert is not reflected in the identity. In a world where evidence exists supporting the existence of an environmental Kuznets curve, and also strongly linking affluence to environmental problems, and where affluence is itself highly unequally distributed (across and within countries), privileging aggregate population as the variable of choice is deeply problematic. The world view that attributes causality to population growth without attention to distribution is a typically Malthusian one, and has been problematic since the time of Malthus himself.² IPAT was also problematic in its day because it focused on growth rates rather than levels, an approach that has since been challenged by fast-growing developing countries and reflected in agreement about ‘common but differentiated responsibilities’ at the Rio Conference in 1992. This agreed principle is now under attack by the global North.

Despite the criticism it has received, IPAT has continued to influence thinking for over forty years. More recent approaches to the links between population, environment and consumption have used more sophisticated modelling and data sets and have gone beyond IPAT to address the challenge of distribution explicitly. O’Neill et al. (2010) use a computable general equilibrium model—the so-called PET (population-environment-technology) model—to compute the energy use and climate change impacts of population growth, ageing and urbanization. The PET model assumes that households affect energy use directly through their consumption patterns, and indirectly through their impact on labour supply and economic growth. The model uses household survey data on composition and consumption to assess the impact of population dynamics. Another model (Chakravarty et al. 2009), takes explicit account of distribution by distinguishing high-CO₂ lifestyles in *all* countries, and uses this to allocate differentiated responsibility for emissions reductions on an individual rather than a country basis.³

The sophistication of these models and the data they build on makes them more attractive and plausible than the simplistic ones that preceded them. Nonetheless, it must be remembered that these models are not truly dynamic in that they assume that existing consumption relationships will also hold in future, although different scenarios for the relationships may be spelled out. For example, are historical patterns of urban energy consumption necessarily a good predictor of the future? What if the pressures of urbanization itself resulted in lowered consumption patterns (i.e. there are downward shifts in the urban consumption function over time)? What if the current deep global economic crisis or the triple crises of finance, food and fuel dampens economic growth prospects in both high and low-income countries over the medium term?

Another limitation of computable general equilibrium models like PET is in their assumptions about the causal links between population dynamics, labour productivity and economic growth, in which the former drive the latter. The models do not recognize that economic growth may well be driven by macroeconomic forces unleashed by global financial or other markets that have little to do with population age structure, labour force availability or other aspects of population dynamics, either globally or for any particular country or region. These may render irrelevant any past observations about such relationships and make them unstable and unreliable.

A great deal also depends on whether the sharp increases in economic inequality that have been recently observed in some of the fastest growing economies are only relative or, at least in some instances, may indicate a rise in absolute levels of poverty for some. Undoubtedly, growth of population will always result in greater resource use (except if it is counter-weighted by a corresponding and opposite reduction in per capita consumption). But a focus on growth rates should not mask the continued importance of levels of consumption and the history of huge inequalities therein. This history matters and continues to matter for large numbers of people despite the rise in affluence in some hitherto poor large countries.

Over the past century, developed countries (home to only 20 percent of the world's population) have been responsible for over two thirds of the net carbon emissions from fossil fuel burning and land use changes (Baumert et al. 2002). Breaking this down further, of the top 20 historical emitters, only four (namely China, India, Mexico and South Africa) are developing countries. China and India, home to 40 percent of the world's people and among the countries with recent experiences of fast economic growth, have contributed only 7 and 2 percent respectively since 1900 (see Figure 1).

FIGURE 3. ESTIMATED PER-CAPITA MORTALITY FROM CLIMATE CHANGE, 2000

Source: Patz et al. 2007.

The South Centre, an intergovernmental think tank of developing countries, has calculated the total global carbon ‘space’ as a measure of the inequitable share that industrialized countries have used up and is no longer available to developing countries (South Centre 2009). Estimates of carbon space usage suggest that a maximum of 2,000 to 2,100 gigatonnes of carbon dioxide is the allowable total of all emissions that would keep the rise in global temperature below the tipping point of 2 degrees Celsius. Between 1880 and 2010, about 1,300 gigatonnes of CO₂ were emitted almost entirely by industrialization in the North. This leaves only around 750 gigatonnes, which at the current rate of a 40 gigatonne rise in emissions per year in both North and South combined will use up the carbon space in the atmosphere within two decades. At the heart of the UN climate change negotiations is a struggle over how much carbon space developed countries have consumed, and their historical responsibility for having contributed most of the emissions. To pay back their emissions debt, developed countries would have to both cut emissions by 100 percent and compensate developing countries through, for example, contributions to adaptation.

Two maps illustrate the inequities in terms of the proportion of carbon emissions by country and the likely impacts of climate change on per capita mortality (see Figures 2 and 3).

While climate negotiations remain deadlocked over reducing emissions and financing commitments, the harsh reality is that the bulk of the effects of climate change will be felt in the poorest countries. The poorest people—disproportionately women—will suffer most and first from droughts, floods, sea rise, famines, water shortages and disease exposures, as well as related conflicts that will likely ensue (see Figure 4).

Meanwhile, some demographers, environmentalists and development analysts have related world population projections to environmental ones, and are predicting a bleak future. Citing factors such as climate change projections, chronic water scarcity and less land under cultivation, they have questioned the capacity of planetary resources to meet peoples’ needs, including whether food production can keep pace with rising populations

(Engelman 2011). They argue that, despite significant reductions in the total fertility rate to near replacement levels in many low- and middle-income countries, population growth will still continue because of the impact of young age structures—the so-called ‘momentum effect’ (Bongaarts 1994)—and there are some parts of the world (mainly sub-Saharan Africa) where fertility rates continue to be high. However the extent of the decline in fertility rates can be seen in Figure 5, and account must be taken of continuing disparities in resource distribution and consumption rates between and within countries, and the impact of economic crises (unrelated to population growth) on the volatility of global commodity markets causing unpredictable spikes in food and fuel prices.

Should the concern today be about the effects of population on the environment or should we focus on the impact of climate change (caused by unsustainable and historically unequal patterns of production and consumption) on people, including large-scale displacement, new infectious diseases, poverty and the destruction of ecological commons? What effects will these have on standard population variables such as life expectancy, fertility and migration?

The latest and most elaborate attempt to gather the evidence on population’s macro-links to the environment is the recent report by the Royal Society, *People and the Planet* (2012), in the lead up to the Rio+20 processes, intended to generate renewed global commitment to addressing environmental challenges. The report moves significantly forward in its recognition of inequitable consumption, and in drawing on the most sophisticated of recent modelling on environmental change. It is also useful in that it recognizes the need both to increase per capita consumption for those living in extreme poverty, and to reduce the consumption of those in high-income countries.⁴ But in some fundamental ways the report is flawed: its authors include very few social scientists (excluding neoclassical economists) and, possibly as a result, it misses the opportunity to provide an analysis of the political economy of either environmental or demographic change, or to take a micro- approach that would explain the actual behaviour of individuals or groups differentiated by economics, gender, age or other markers.

Most crucially, the report is distinctly ‘pre-Cairo’ in its approach to such issues as gender equality, health or women’s human rights. Its main recommendation in this context is to stress the importance of girls’ education as instrumental to fertility reduction. As we argue below, the population field has moved a long way from this in the last two decades.

CHALLENGES TO THE PARADIGM: A WORM’S EYE VIEW ON POPULATION AND SUSTAINABILITY

Challenges to the dominant Malthusian paradigm on the relationship between population, economic growth and the environment have critiqued both the logic of its arguments, and also put forward uncomfortable evidence about its purported connections, as is clear from the previous section. Social scientists have offered a third strand of critique, questioning the paradigm’s approach to population, which is largely based on macro-level data and relationships without reference to the micro-level reality of the lives of poor people. In the lead up to the Cairo conference of 1994, the South feminist network, Development Alternatives with Women for a New Era initiated a collaborative research project with the International Social Science Council and the Social Science Research Council that brought together researchers and activists with the explicit objective of rethinking the population-environment debate by “identifying and examining the micro-level linkages between population and environment and relating these to macro-level considerations” (Arizpe et al. 1994). The effort resulted in a book, *Population and Environment—Rethinking the Debate*.

The editors argued for moving beyond a “polarized debate which ultimately poses an impossible choice for policy makers—a choice between people’s needs and wants, and the conservation of the environment” (Arizpe et al. 1994). They went on to say:

The debate has failed to benefit from the wealth of data generated at the micro level—data which provide rich information on the social and economic factors that mediate the relation between population and the environment...the population problem does not just involve absolute numbers of people nor even just population densities or overall rates of increase, but also, in important ways, social, political, and institutional factors. Complex patterns of human relationships overlay, alter and distort the relation of people to the land and to the cities... The cultural, social and political filters through which the environment is interpreted and viewed (for example the concept of ‘desertification’) are also crucial to the social science understanding of ecology and environment.

Different papers in the volume focus on the way in which the researcher's world view and approach affect the questions asked and the evidence gathered, and how social, political or economic factors shape how a person uses and manages natural resources. This is true *a fortiori* for women who, because of the gendered division of labour that assigns to them the main responsibilities for the care economy (domestic work, care of human beings and social reproduction), are often the stewards of local ecologies, including food production, and therefore most severely affected by environmental damage and resource loss. A number of the papers were on deforestation, and together they showed:

The links between environmental problems, human activities and issues of population are rarely direct. It is clear that social scientists must carefully re-examine social, economic and political processes from the point of view of their potential environmental impacts. Models that accomplish this would include mechanisms that govern the use, access and control of resources, as well as the allocation of costs and benefits of human activities exploiting those resources.

Since the period when the book was published, there has been a wealth of research, mostly but not only based on developing countries, which starts from the micro-basis of how people actually live, produce and consume for their livelihoods, use resources, and conserve or abuse local ecologies. The work of Agarwal, Leach, Ostrom, Peluso and Watts, Ribot, Rocheleau among others provides some important examples (Agarwal 2010, Leach et al. 1999, Ostrom 2000, Peluso and Watts 2001, Ribot and Peluso 2003, Rocheleau 1996). While some of this research has influenced the 'people versus planet' debate, a critical element—the place of gender relations in population dynamics and human ecology—is not always recognized in the resurgence of Malthusian approaches.

ENTER HUMAN RIGHTS: WOMEN TRANSFORM THE PARADIGM

The previous section has argued that the more micro-level approaches and complex behavioural interactions studied by social scientists bring in new and varied evidence, which is not easy to take account of in large-scale macro-level models of the links between environment and population. An even greater paradigmatic change has been brought about by the work of feminist researchers and women's organizations.

Sen (2006) argues that women's struggle for control over their bodies is currently in its second phase. The first phase occurred during the birth-control movement of the late nineteenth and early twentieth centuries. This movement was interwoven with the suffragist struggle for the recognition of women as citizens in Europe and North America, and to some extent the anti-colonial movements of that time, although the

relationship was by no means straightforward. The period between the first phase and the second phase that began about 30 years ago saw the population policy field and the discipline of demography grow substantially.

Population policy, as it evolved in the period after the Second World War, was largely Malthusian. Talk of a ‘population bomb’ fed concerns in the policy establishment of the global North about the growing numbers of non-white people. Population growth was portrayed as the single most serious threat to economic development, and population control was put forward as the policy answer (Ehrlich 1971). Despite the South-versus-North skirmishes over the relative importance of ‘development’ versus family planning in controlling population growth,⁵ there was very little real challenge to this consensus about population policy.

Though anthropologists and other social scientists have had some influence, demography developed as a largely technical discipline concerned with the calculus of birth, death and migration, with much less interest in social and behavioural issues. Perhaps for this reason, the field as a whole was largely able to close itself off from attention to the causes and consequences of sexual and reproductive behaviour, and the social institutions, practices and norms within which that behaviour is embedded in different cultures and societies. It was not until the rise of the modern women’s movement in the 1960s and 1970s that real change became possible in the field.

The international women’s movement had coined and been using the term ‘reproductive rights’ for about 20 years before the paradigm shift that transformed the population field at the International Call on Population Development in Cairo in 1994. Much of this work was motivated by activist concern to challenge coercion, human rights abuses and unethical practices in population policies and programmes.⁶ A strong focus of this work was to challenge the ways in which new contraceptive technologies were introduced in family planning programmes and the problem of coercion and quality of services, as well as the problem of inadequate access to contraception or safe abortion services. This activism was not matched by significant feminist research effort until the 1990s. During the 1980s, feminist demographers remained concerned with the question of whether and through which pathways women’s education or autonomy can affect fertility and related behaviour (Mason 1988).

POPULATION, ENVIRONMENT AND GENDER

The UN conferences of the 1990s galvanized both research and activism. In the lead up to the Earth Summit, many major North-based environmental groups posited population growth as a major threat to the earth’s carrying capacity. Feminist activists began a

process of consolidation of a counter-position that was articulated in the *Planeta Femea*, the women's tent, through interactions with a large number of women from environmental organizations. In the next two years, women's organizations worked together to develop a consensus position on population policy that would bridge the considerable differences and mistrust that existed among groups from different regions and backgrounds. While some of these differences were the product of mistrust of Northern by Southern civil society groups, there were also tensions among groups within each global pole. A major and conscious effort at bridging gaps and building agreement was critical in allowing the women's movement to turn its attention to two tasks: the first was to negotiate an alliance with the family planning lobbies, and the second was to develop the political capacity to challenge the growing bloc of religious conservatives that was being created by the Vatican. The success of the women's movement in accomplishing these two tasks is the history of the International Conference on Population and Development.

A new framework for population-related policy was created, which affirmed women's right to control their fertility and meet their needs for safe, affordable and accessible contraceptives, while recognizing the social determinants, and health and rights consequences of sexual and reproductive behaviour (Sen et al. 1994, Correa and Reichmann 1994, Dixon-Mueller 1993). New and radical concepts, such as reproductive and sexual health and rights, had to be clarified in a field that had been an "odd mixture of technocratic modelling and doomsday scenarios until then" (Antrobus and Sen 2006). The result of all this effort was the paradigm change of the International Conference on Population and Development, as detailed in its Programme of Action—the shift away from a policy focus on aggregate numbers and population growth towards a focus on sexual and reproductive health and rights (including contraception and family planning) and gender equality.

While there was no intrinsic disagreement between the women's groups and the environmental groups in terms of the importance of and need for high quality, effective contraceptive services, there were other differences. These were about overarching goals: macro-level planetary sustainability versus the health and rights of people, particularly of women and young people. These differences in goals meant that each approach asked different questions and marshalled different evidence. For example, family planning programmes in India had for a long time explained away the poor uptake of intra-uterine contraceptive devices as being due to women's ignorance and unscientific traditional beliefs. This was because they did not actually focus attention on women's reproductive health and rights. It was only after the focus on women's reproductive health generated evidence about high rates of reproductive tract infections among poor rural women (Bang 1989) that their reluctance to use the devices became acknowledged as being rational and sensible.

CONCLUSION: CHALLENGES OF RIO+20 AND CAIRO+20

These differences in approaches and evidence came to a head in the lead up to the Rio and Cairo conferences. Macro-level approaches linking the natural sciences with traditional demography tended to oversimplify the causes and consequences of both demographic and ecological change. More nuanced social science and political economy approaches brought less simplistic analysis but also raised more difficult questions about needed policies and changes. It was here that women's organizations provided the radical shift in approach that led to the change of the population paradigm. Up until Cairo, the main question asked about women's role in population change was whether and the extent to which girls' education would alter fertility behaviour, and thereby population growth. But Cairo moved population thinking from such *instrumentality* to a human rights basis for policies that assigned *intrinsic* value to gender equality and women's sexual and reproductive health and autonomous decision-making. It opened up and made possible a range of new questions about policies, programmes and ethics that demographers had not been asked before.

The engagement between women's and environmental groups dampened the macro approaches to population and environment for well nigh two decades after the Rio and Cairo conferences. More recently, however, in the lead up to the intergovernmental negotiations on climate change and the review of the Kyoto Protocol, such approaches have resurfaced, raising human rights concerns about the implications for global consensus about population policies and programmes. They also appear to have come back in major reports such as that of the Royal Society (2012), albeit in a much more nuanced and sophisticated manner. Some of this may be simply because many environmentalists are natural scientists for whom the complexities of social science approaches may be unsettling. But it may also be the case that, in the difficult context of bitter South-versus-North battles over climate change, common but differentiated responsibilities for current environmental problems, and reaffirmation of the core principles of the Earth Summit, the bogey of population growth may serve to diffuse the call for recognizing historical responsibilities. Caught in the middle of these battles is the continuing struggle for the realization of women's human rights, including their sexual and reproductive rights and gender justice.

Marrying a human rights-based approach to population and environmental change is not easy by any means. But when both population and environment, and the links between them, are examined from the perspective of women, gender equality, human rights and social justice, not only can new questions be asked but new approaches can be taken and new policy and programme answers given. For example, the intergovernmental negotiations during the 45th session of the UN Commission on Population and Development held in April 2012 resulted in a remarkably progressive recognition of the needs, health and human rights of adolescents and young people (UNCPD 2012). This is the direction that the paradigm change of Rio, Vienna, Cairo and Beijing needs to follow for its completion. ■

PROMOTING A GENDER-INCLUSIVE GREEN ECONOMY

Bina Agarwal

UN Photo/Logan Abassi

Rapid economic growth in many developing countries, in recent years, has failed to translate into adequate gains in terms of gender inclusion and environmental sustainability. Recent research demonstrates however, that women's inclusion in green governance could prove to be a win-win situation in promoting a green growth.

In my study of community forestry groups in India and Nepal, I examined what difference women's presence makes in these institutions.¹s. How does it affect institutional functioning and outcomes for conservation and subsistence? And how much presence is needed to make a real difference? This approach represented an important departure from most existing research on gender and local forest governance, which had focused almost entirely on women's *absence* from governance and on the implied inequality, and paid little attention to the impact of women's presence.

Based on a sample of 135 community forestry groups, protecting local forests in three districts of Gujarat, India, and three districts of Nepal, I found that groups with a larger proportion of women in their executive committees performed significantly better than those with few or no women, in several important respects.

For example, in mixed-gender executive committees (a typical executive committee has 11 members), women's attendance rate in meetings was significantly higher where they constituted 25 to 33 percent of the members, than if they constituted less than 25 percent. The likelihood of at least some women speaking up was also greater among committees with a third or more women members, as was the likelihood of women holding significant office (e.g. president, vice president, secretary). This empirically supports the popular view that a critical mass of one quarter to one third of women is needed for their presence to make a difference in decision-making bodies, and strengthens the policy argument for promoting at least these proportions in such bodies.

Including landless women makes a particular difference. Contrary to the popular view that the poorest are least likely to participate in public forums, I found that poor women, if present in sufficient numbers on an executive committee, were more likely to attend meetings and speak up than women from well-off households, since they had less to lose in terms of social status by crossing social norms, and much to gain if the decisions went in their favour.

Most importantly, women's presence significantly improved forest conservation outcomes. I compared groups with more than two executive committee women members and those with two women or less

in Gujarat, and groups with all-women committees and other groups in Nepal. By most assessments of forest condition (the forest department's records, villagers' assessment, research team's assessment, and satellite data, where available), groups with more women committee members in Gujarat and those with all-women committees in Nepal substantially outperformed other groups, showing better forest regeneration and improved canopy cover since protection began, after controlling for other factors. This was especially striking in Nepal, where forests with all-women executive committees showed a 51 percent greater likelihood of improved forest condition than other groups, despite receiving much smaller and more degraded forest plots to protect.

These positive conservation effects are attributable to several factors. Women are the main subsistence users of forests for firewood, fodder and supplementary food. Including them in an executive committee enlarges the pool of people committed to resource conservation. It improves information flows about forest closure rules (which restrict entry and regulate extraction from the protected area) among a wider cross-section of users. It increases the numbers keeping watch. And it enables women to better use their knowledge of local ecology and conservation practices on the protected plots. Older women, who tend to have more authority and experience, make a particular difference. Moreover, women's involvement can better raise children's awareness about conservation practices and so enhance long-term institutional sustainability. The forest department's technical support can also bring benefits, if they

reduce the current gender gap in access to training.

In addition, many gender-empowering effects follow. Speaking at meetings, influencing decisions, patrolling, holding office, sometimes even asking forest officials for a forest plot to protect, are all facets of empowerment. Measures that increase women's presence would thus bring both intrinsic benefits, in terms of equitable participation, and instrument advantage by better fulfilling conservation and subsistence objectives.

Scaling up these initiatives is possible by forming federations of forest users, such as the Federation of Community Forest Users Nepal, which is country-wide and mandates that 50 percent of its office-bearers be women. Also, in the long run we need policies to reduce local dependence on forests by promoting alternative cooking fuel, such as biogas; alternatives to wood for agricultural implements and house repair; and alternative means of livelihood. Forest federations with their wide community networks could play an important role in bringing about such shifts.

Forests are carbon sinks and critical sources of biodiversity. These results demonstrate effective ways of promoting green growth and a green economy in a gender-inclusive way. ■

CAN ECONOMIC GROWTH SUPPORT GENDER EQUALITY AND ENVIRONMENTAL SUSTAINABILITY?

Diane Elson

Economic growth cannot support gender equality and environmental sustainability if it continues to privilege the demands of a wealthy elite, degrade the commons, deplete public services, make the luxury shopping mall the icon of development, and encourage women to turn themselves into commodities.

However, economic growth can support gender equality and environmental sustainability if what grows, are gender-equitable production systems and products that respect, protect and fulfil human rights (economic, social, cultural, civil and political); that respect, protect and conserve the environment; and that enable people to be self-determining rather than have their sense of self and aspirations shaped by big business.

We need to dethrone GDP, which measures production by a market-oriented money metric, and use new measures that encompass the quality, not just the quantity, of production systems and products, including measures that recognize that the amount of time spent in producing something is not just a cost to be reduced but frequently a contributor to the quality

of the product. This is especially important in service provision, paid and unpaid care services in particular.

Organizations working to realize women's rights and improve their wellbeing need to identify the production systems and products that should expand, and those that should contract. Pursuing these goals requires identifying the economic and social policies that will support these objectives. Though market incentives have some role to play, achieving these objectives cannot be left to the market. Though private sector for-profit entrepreneurs must contribute, support must be given to a range of other providers, such as cooperatives and other forms of collective provision, and democratically organized public-sector services.

In identifying products and policies, we can draw on feminist research regarding how different economic models meet the needs of the world's low-income women in taking care of themselves, their families and their communities.¹ This knowledge is rooted in the everyday realities of women's lives, recognizing the contributions that

UN Photo/Khae Park

women make through the unpaid work of caring for families and communities, as well as paid work producing for the market or the public sector.

What needs to expand includes access to clean water and sanitation, renewable energy, carbon-neutral housing adapted to local climate conditions, effective public transport, secure and nutritious food supplies, high quality public services for education; access to health and care for children, sick people and frail elderly people; and to information and communication systems—all of which would benefit women. If access is to be affordable and products are to be of high quality, it cannot be left to the market. There must be safeguards for a variety of channels for access, including production for own use, production by civil society organizations, and production by public sector agencies of service free at the point of delivery. Production by big business must be democratically regulated, and whistle blowers and watch dogs supported, to guard against regulators becoming subservient to the interest they are meant to regulate.

The expanding systems of production must provide decent work that recognizes that both men and women workers have care responsibilities for their families and communities, and which enables them to combine paid and unpaid work. Unemployment and underemployment must be addressed with the creation of sustainable jobs. There are many unmet needs in the care of people and the environment, and many people available to meet these needs, given appropriate training and adequate remuneration. What is missing, are the economic

policies that will support the creation of decent jobs, and employ people to meet these needs.

That is because economic policies privilege products and production systems that we need less of—big cars that use a lot of fuel; armaments; luxury apartments that require air conditioning; water-thirsty golf courses; sex tourism; fast food and highly processed food that creates obesity and diabetes; financial systems oriented to high bonuses for the few and high risks for everyone else; and production systems oriented to treating most people as disposable components for generating profits.

But this is not inevitable. It can be changed. People are already working in many parts of the world to bring about that change, with women in the forefront in many cases.² The pressures of climate change and ecological crisis make this change even more urgent. The question that needs to be addressed is not growth versus no growth, but growth of 'goods', complemented by contraction of 'bads', with measures to create more decent employment in the production of 'goods', to which people can be channelled as employment in the production of 'bads' declines. The knowledge of low-income women, who spend so much time caring for their families and communities, will be especially valuable in identifying which are the 'good' products, and which the 'bad' products. ■

GENDER EQUALITY CASE STUDY: THE BODY SHOP

Christina Archer

When Anita Roddick founded The Body Shop in the 1970s, her way of doing business was ahead of its time; she passionately believed that businesses should deliver social change. Five core values—Support Community Fair Trade, Defend Human Rights, Against Animal Testing, Activate Self-esteem and Protect Our Planet—underpin how The Body Shop does business. To further these values, The Body Shop established the cosmetic industry's first fair trade programme, Community Fair Trade (originally Trade Not Aid). The industry's largest programme, it buys accessories and ingredients from 25 producer groups in 21 countries. The programme benefits thousands of people by providing, among other things, participatory price setting, transparent forecasts and stable long-term demand. The Body Shop support has been instrumental to many groups' efforts to build and expand their businesses beyond initial demand.

In 2009, The Body Shop updated the programme's operational framework and developed the Community Fair Trade Charter. The Charter, based on the principles of fair trade, incorporates the International Labour Organization's core principles of labour rights, as interpreted in the Ethical Trading Initiative's Base Code. It also includes more explicit commitments for the

company and its suppliers to understand production's impacts on environmental sustainability and biodiversity, in order to put in place systems to manage and reduce these. The Charter codifies The Body Shop's commitments as a fair buyer, and producers' responsibilities as Community Fair Trade suppliers.

One of the longest-standing Community Fair Trade relationships is with the Juan Francisco Paz Silva cooperative, in Achuapa, northern Nicaragua. The cooperative was set up over 20 years ago, and works to support its over 270 member families develop sustainable livelihoods. Although women have been involved in the cooperative from the start, and are represented on the elected Board, they did not join as members in their own right, as traditionally the head of the family (in majority of cases the man) would be the family representative.

Achupan farmers have traditionally grown maize, beans and sorghum as subsistence crops, and sesame as a cash crop. Sesame, one of the world's oldest commercial oil crops, has been used in cosmetics for thousands of years. The Body Shop started trading with the cooperative in 1992, becoming its first international client. Inclusion in the Community Fair Trade programme provided

The Body Shop follows a business model that is based on having a supply chain that not only delivers high-quality products, but also maximizes community-level development impacts.

cooperative members with the support needed to upgrade their production and quality control processes, increasing the volume and quality of their sesame seed oil. Today, cooperative members have a portfolio of international clients and have moved up the supply chain, joining with other local cooperatives to form their own export/import company.

In 2009, the cooperative suggested piloting a pioneering fair pricing model that incorporates women's unpaid labour—labour that is essential to the functioning of a productive household unit growing sesame. This work not only takes into account traditional activities in the home, but also acknowledges tasks such as seed grading that is done at home and may fall out of traditional pricing models based on labour hours worked on the land. The funds generated by this additional premium are put into the Anita-Maria Zunilda Women's Fund, a revolving loan fund that is only accessible to women in the community. The fund has enabled over 70 women, currently organized into eight small community enterprise groups, to carry out small-scale income generating activities both individually and as a group.

Although the fund has only been operational for a few years, the women already describe its impacts on their lives: for the first time they are in control of the money they are earning and saving, and have been able to access credit to set up their own economic initiatives (due to assets being held in their husband's names women lack the collateral to access loans from traditional sources). This

programme has increased the women's empowerment and self esteem, and has resulted in a marked increase in women wanting to join the cooperative.¹

The Body Shop follows a business model that is based on having a supply chain that not only delivers high-quality products, but also maximizes community-level development impacts. This business model—by recognizing women's role in the supply chain, acknowledging the interdependence of women's and men's paid and unpaid work, creating a fund to rebalance income distribution within producer households, and increasing the income generated and held by women—has improved intra-household food security and households' resilience to changing environments.

Following this model and building close relationships with producer groups can ensure long-term security of supply for the buying company and can inform purchasing practices that ensure that the benefits of trade are equitably shared at the community and household level. This visibility is also important for companies that are beginning to understand how climate change will affect producer communities, and how unfair purchasing practices can exacerbate these impacts. ■

Endnotes

- 1 To evaluate the benefit of this innovative pricing model for women in this supply chain, The Body Shop is co-funding a PhD through the ESRC Collaborative Award, held at Royal Holloway, University of London. For more information visit <http://womenincommunitytrade.org>.

GENDER EQUALITY, ENERGY AND CLIMATE CHANGE
